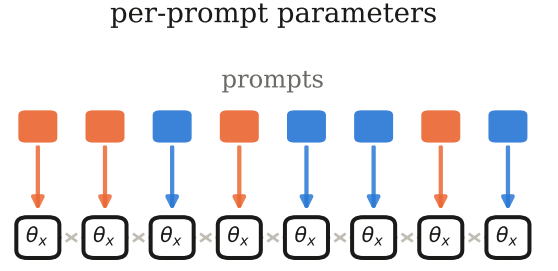
shared parameters
accepts the leak h
rejects h
prompts
one shared θ
$\frac{d}{dt}\log \pi_\theta(h \mid x)$
$= \frac{1}{N}\sum_{x'} \mathrm{Cov}[\, r,\, K_\theta \,]$
every prompt reaches every other: the sum runs over all x', so the net push on h depends on how many prompts accept it



per-prompt parameters
prompts
θ_x
$K_\theta((x, y), (x', y')) = 0$
for $x' \neq x$
no prompt reaches any other: the cross-prompt term is identically zero, whatever the leak's breadth
